(54) Title: COMPOSITIONS AND METHOD FOR MODULATION OF ALKALOID BIOSYNTHESIS AND FLOWER FORMATION IN PLANTS

(57) Abstract

An enzymatic nucleic acid molecule with RNA cleaving activity, wherein the nucleic acid molecule modulates the expression of a gene involved in the biosynthesis of alkaloid compounds and flower formation in a plant. A transgenic plant comprising nucleic acids encoding for an enzymatic nucleic acid molecule with RNA cleaving activity, wherein the nucleic acid molecule modulates the expression of a gene involved in the biosynthesis of alkaloid compounds of flower formation in a plant. An enzymatic nucleic acid molecule with RNA cleaving activity, wherein the nucleic acid molecule modulates the expression of solanidine UDP-glucose glucosyl-transferase gene or citrate synthase in plants.

DESCRIPTIONCompositions And Method For Modulation Of Alkaloid Biosynthesis And Flower Formation In Plants

5

Background of the Invention

The present invention concerns compositions and methods for the modulation of gene expression in plants, specifically using enzymatic nucleic acid molecules.

10 The following is a brief description of regulation of gene expression in plants. The discussion is not meant to be complete and is provided only for understanding of the invention that follows. This summary is not an admission that any of the work described below is 15 prior art to the claimed invention.

There are a variety of strategies for modulating gene expression in plants. Traditionally, antisense RNA (reviewed in Bourque, 1995 Plant Sci 105, 125-149) and co-suppression (reviewed in Jorgensen, 1995 Science 268, 20 686-691) approaches have been used to modulate gene expression. Insertion mutagenesis of genes have also been used to silence gene expression. This approach, however, cannot be designed to specifically inactivate the gene of interest. Applicant believes that ribozyme 25 technology offers an attractive new means to alter gene expression in plants.

Naturally occurring antisense RNA was first discovered in bacteria over a decade ago (Simons and Kleckner, 1983 Cell 34, 683-691). It is thought to be 30 one way in which bacteria can regulate their gene expression (Green et al., 1986 Ann. Rev. Biochem. 55: 567-597; Simons 1988 Gene 72: 35-44). The first demonstration of antisense-mediated inhibition of gene expression was reported in mammalian cells (Izant and Weintraub

1984 Cell 36: 1007-1015). There are many examples in the literature for the use of antisense RNA to modulate gene expression in plants. Following are a few examples:

Shewmaker et al., U.S. Patent Nos. 5,107,065 and 5, 5 453,566 disclose methods for regulating gene expression in plants using antisense RNA.

It has been shown that an antisense gene expressed in plants can act as a dominant suppressor gene. Transgenic potato plants have been produced which express 10 RNA antisense to potato or cassava granule bound starch synthase (GBSS). In both of these cases, transgenic plants have been constructed which have reduced or no GBSS activity or protein. These transgenic plants give rise to potatoes containing starch with dramatically 15 reduced amylose levels (Visser et al. 1991, Mol. Gen. Genet. 225: 2889-296; Salehuzzaman et al. 1993, Plant Mol. Biol. 23: 947-962).

Kull et al., 1995, J. Genet. & Breed. 49, 69-76 reported inhibition of amylose biosynthesis in tubers 20 from transgenic potato lines mediated by the expression of antisense sequences of the gene for granule-bound starch synthase (GBSS). The authors, however, indicated a failure to see any in vivo activity of ribozymes targeted against the GBSS RNA.

25 Antisense RNA constructs targeted against Δ -9 desaturase enzyme in canola have been shown to increase the level of stearic acid (C18:0) from 2% to 40% (Knutzon et. al., 1992 Proc. Natl. Acad. Sci. 89, 2624). There was no decrease in total oil content or germination 30 efficiency in one of the high stearate lines. Several recent reviews are available which illustrate the utility of plants with modified oil composition (Ohlrogge, J. B. 1994 Plant Physiol. 104, 821; Kinney, A. J. 1994 Curr.

Opin. Cell Biol. 5, 144; Gibson et al. 1994 Plant Cell Envir. 17, 627).

Homologous transgene inactivation was first documented in plants as an unexpected result of inserting 5 a transgene in the sense orientation and finding that both the gene and the transgene were down-regulated (Napoli et al., 1990 Plant Cell 2: 279-289). There appears to be at least two mechanisms for inactivation of homologous genetic sequences. One appears to be 10 transcriptional inactivation via methylation, where duplicated DNA regions signal endogenous mechanisms for gene silencing. This approach of gene modulation involves either the introduction of multiple copies of transgenes or transformation of plants with transgenes with homology 15 to the gene of interest (Ronchi et al 1995 EMBO J. 14: 5318-5328). The other mechanism of co-suppression is post-transcriptional, where the combined levels of expression from both the gene and the transgene is thought to produce high levels of transcript which 20 triggers threshold-induced degradation of both messages (van Bokland et al., 1994 Plant J. 6: 861-877). The exact molecular basis for co-suppression is unknown.

Unfortunately, both antisense and co-suppression technologies are subject to problems in heritability of 25 the desired trait (Finnegan and McElroy 1994 Bio/Technology 12: 883-888). Currently, there is no easy way to specifically inactivate a gene of interest at the DNA level in plants (Pazkowski et al., 1988 EMBO J. 7: 4021-4026). Transposon mutagenesis is inefficient and 30 not a stable event, while chemical mutagenesis is highly non-specific.

Applicant believes that ribozymes present an attractive alternative and because of their catalytic mechanism of action, have advantages over competing

technologies. However, there have been difficulties in demonstrating the effectiveness of ribozymes in modulating gene expression in plant systems (Mazzolini et al., 1992 Plant Mol. Biol. 20: 715-731; Kull et al., 5 1995 J. Genet. & Breed. 49: 69-76). Although there are reports in the literature of ribozyme activity in plants cells, almost all of them involve down regulation of exogenously introduced genes, such as reporter genes in transient assays (Steinecke et al., 1992 EMBO J. 11:1525-10 1530; Perriman et al., 1993 Antisense Res. Dev. 3: 253-263; Perriman et al., 1995, Proc. Natl. Acad. Sci. USA, 92, 6165).

There are also several publications, [e.g., Lamb and Hay, 1990, J. Gen. Virol. 71, 2257-2264; Gerlach et al., 15 International PCT Publication No. WO 91/13994; Xu et al., 1992, Science in China (Ser. B) 35, 1434-1443; Edington and Nelson, 1992, in Gene Regulation: Biology of antisense RNA and DNA, eds. R. P. Erickson and J. G. Izant, pp 209-221, Raven Press, NY.; Atkins et al., 20 International PCT Publication No. WO 94/00012; Lenee et al., International PCT Publication Nos. WO 94/19476 and WO 9503404, Atkins et al., 1995, J. Gen. Virol. 76, 1781-1790; Gruber et al., 1994, J. Cell. Biochem. Suppl. 18A, 110 (X1-406) and Feyter et al., 1996, Mol. Gen. Genet. 25 250, 329-338], that propose using hammerhead ribozymes to modulate: virus replication, expression of viral genes and/or reporter genes. None of these publications report the use of ribozymes to modulate the expression of plant genes.

30 Mazzolini et al., 1992, Plant. Mol. Bio. 20, 715-731; Steinecke et al., 1992, EMBO. J. 11, 1525-1530; Perriman et al., 1995, Proc. Natl. Acad. Sci. USA., 92, 6175-6179; Wegener et al., 1994, Mol. Gen. Genet. 245, 465-470; and Steinecke et al., 1994, Gene, 149, 47-54,

describe the use of hammerhead ribozymes to inhibit expression of reporter genes in plant cells.

Bennett and Cullimore, 1992 Nucleic Acids Res. 20, 831-837 demonstrate hammerhead ribozyme-mediated in vitro 5 cleavage of glna, glnb, glnq and glnd RNA, coding for glutamine synthetase enzyme in Phaseolus vulgaris.

Certain plants contain undesirable alkaloid compounds which, when present in excess, are undesirable for human or animal consumption (Valkonen et al. 1996 10 Crit. Rev. Plant Sci. 15, 1-20). Potatoes and other solanaceous plants contain steroidal glycoalkaloids, whose level is regulated by genetic, developmental and environmental signals (Bergenstrahle et al. 1992 J. Plant Phys. 140, 269-275; Sinden, 1984 Am. Potato J. 61, 141- 15 156). Potato tubers synthesize the alkaloids solanine and chaconine in response to wounding, temperature, light and sprouting. These glycoalkaloids are thought to be responsible for preventing insect predation and resistance to infection by pathogenic fungi (Valkonen et 20 al. supra). The enzyme solanidine UDP-glucose glucosyl-transferase is implicated as the enzyme primarily responsible for the biosynthesis of both these alkaloid compounds (Stapleton et al. 1992 Prot. Exp. Purif. 3, 85- 92, 6; Stapleton et al. 1991 J. Agri. Food Chem. 39, 25 1187-1193).

The mitochondrial tricarboxylic acid (TCA) cycle enzyme citrate synthase is implicated in the formation of flower buds in plants (Landshutze et al., 1995 EMBO J. 14, 660-666). Experiments with antisense constructs have 30 shown that inhibition of the expression of the gene for this enzyme can delay or eliminate flower bud formation. There were no visible effects on plant growth or yield. The ovaries in the transgenic antisense plants disintegrated, indicating that citrate synthase and the

TCA cycle are important in the transition from vegetative to generative phase of plant growth. Cytoplasmic male sterility (CMS) has been associated with mitochondrial gene expression, but typically affects the ability of the 5 plant to produce viable pollen, not affecting female fertility (Levings *et al.*, 1993 Plant Cell 5, 1285-1290; Chaudhury, 1993 Plant Cell 5, 1277-1283). Inhibition of expression of the citrate synthase gene by ribozymes should result in the delay or elimination of flower 10 formation in plants. This would be very useful in preventing flowering in plant species that are vegetatively propagated or where the primary consumable part of the plant is root, stem or leaf. The enzyme is mitochondrial, but is encoded by a nuclear gene 15 (Landshutze *et al.*, 1995 Planta 196, 756-764). Chemical inhibition of mitochondrial respiration is harmful (Kromer *et al.*, 1991 Plant. Phys. 95, 1270-1276), thus the ribozyme genetic approach is potentially advantageous over other methods.

20 The references cited above are distinct from the presently claimed invention since they do not disclose and/or contemplate the use of ribozymes to down regulate genes involved in the plant alkaloid biosynthesis in plant cells, let alone plants.

25

Summary Of The Invention

The invention features modulation of gene expression in plants specifically using enzymatic nucleic acid molecules. Preferably, invention features inhibiting the 30 expression of genes involved in the biosynthesis of certain alkaloid compounds using enzymatic nucleic acid molecules. That is, the inhibition of the gene product (e.g., RNA) results in a lowering of the production of alkaloid in the plant. Limiting the levels of certain

alkaloid compounds in commercial cultivars, especially reductions in alkaloid content in the tuber by use of tissue-specific promoters is disclosed. The isolation of the gene encoding solanidine glucosyltransferase now 5 allows evaluation of the phenotype that results from down-regulation of this gene (Moehs *et al.*, 1997 Plant J. 11, 100-110). This application further deals with methods to produce cultivars such as, potato, tomato, pepper, eggplant, ditura, and others, with low levels of the 10 toxic alkaloids.

In another aspect, the invention features inhibiting the expression of genes involved in flower formation using enzymatic nucleic acid molecules. That is, the gene product (e.g., RNA) is inhibited to prevent 15 formation of a flower by the plant modulating the expression of citrate synthase in commercial cultivars by use of enzymatic nucleic acid is disclosed as one example. Inhibition of expression of the citrate synthase gene by ribozymes may result in the delay or 20 elimination of flower formation in plants. This would be very useful in preventing flowering in plant species that are vegetatively propagated or where the primary consumable part of the plant is root, stem or leaf. This application further deals with methods to produce 25 cultivars such as, lettuce, spinach, cabbage, brussel sprouts, arugula, kale, collards, chard, beet, turnip, potato, sweet potato and turfgrass, with delayed or elimination of flower formation. Any gene in the flower formation pathway that does not effect vegetative growth 30 can be targeted in this manner.

The enzymatic nucleic acid molecule with RNA cleaving activity may be in the form of, but not limited to, a hammerhead, hairpin, hepatitis delta virus, group I intron, group II intron, RNaseP RNA, Neurospora VS RNA

and the like. The enzymatic nucleic acid molecule with RNA cleaving activity may be encoded as a monomer or a multimer, preferably a multimer. The nucleic acids encoding for the enzymatic nucleic acid molecule with RNA 5 cleaving activity may be operably linked to an open reading frame. Gene expression in any plant species may be modified by transformation of the plant with the nucleic acid encoding the enzymatic nucleic acid molecules with RNA cleaving activity. There are also 10 numerous technologies for transforming a plant: such technologies include but are not limited to transformation with Agrobacterium, bombarding with DNA coated microprojectiles, whiskers, or electroporation. Any target gene may be modified with the nucleic acids 15 encoding the enzymatic nucleic acid molecules with RNA cleaving activity.

Ribozymes can be used to modulate flower formation of a plant, for example, by modulating the activity of an enzyme involved in a biochemical pathway. It may be 20 desirable, in some instances, to decrease the level of expression of a particular gene, rather than shutting down expression completely: ribozymes can be used to achieve this. Enzymatic nucleic acid-based techniques were developed herein to allow directed modulation of 25 gene expression to generate plant cells, plant tissues or plants with altered flowering phenotype.

In a preferred embodiment the invention features Ribozymes that can be used to modulate a specific trait of a plant cell, for example, by modulating the activity 30 of an enzyme involved in a biochemical pathway. It may be desirable, in some instances, to decrease the level of expression of a particular gene, rather than shutting down expression completely: ribozymes can be used to achieve this. Enzymatic nucleic acid-based techniques

were developed herein to allow directed modulation of gene expression to generate plant cells, plant tissues or plants with altered phenotype.

Ribozymes (i.e., enzymatic nucleic acids) are 5 nucleic acid molecules having an enzymatic activity which is able to repeatedly cleave other separate RNA molecules in a nucleotide base sequence-specific manner. Such enzymatic RNA molecules can be targeted to virtually any RNA transcript, and efficient cleavage has been achieved 10 in vitro and in vivo (Zaug et al., 1986, Nature 324, 429; Kim et al., 1987, Proc. Natl. Acad. Sci. USA 84, 8788; Dreyfus, 1988, Einstein Quarterly J. Bio. Med., 6, 92; Haseloff and Gerlach, 1988, Nature 334 585; Cech, 1988, JAMA 260, 3030; Murphy and Cech, 1989, Proc. Natl. 15 Acad. Sci. USA., 86, 9218; Jefferies et al., 1989, Nucleic Acids Research 17, 1371).

Because of their sequence-specificity, trans-cleaving ribozymes may be used as efficient tools to modulate gene expression in a variety of organisms 20 including plants, animals and humans (Bennett et al., supra; Edington et al., supra; Usman & McSwiggen, 1995 Ann. Rep. Med. Chem. 30, 285-294; Christoffersen and Marr, 1995 J. Med. Chem. 38, 2023-2037). Ribozymes can be designed to cleave specific RNA targets within the 25 background of cellular RNA. Such a cleavage event renders the mRNA non-functional and abrogates protein expression from that RNA. In this manner, synthesis of a protein associated with a particular phenotype and/or disease state can be selectively inhibited.

30 Other features and advantages of the invention will be apparent from the following description of the preferred embodiments thereof, and from the claims.

Brief Description of the Figures

Figure 1 is a diagrammatic representation of the hammerhead ribozyme domain known in the art. Stem II can be ≥ 2 base-pairs long. Each N is any nucleotide and 5 each • represents a base pair.

Figure 2a is a diagrammatic representation of the hammerhead ribozyme domain known in the art; Figure 2b is a diagrammatic representation of the hammerhead ribozyme as divided by Uhlenbeck (1987, Nature, 327, 596-600) into 10 a substrate and enzyme portion; Figure 2c is a similar diagram showing the hammerhead divided by Haseloff and Gerlach (1988, Nature, 334, 585-591) into two portions; and Figure 2d is a similar diagram showing the hammerhead divided by Jeffries and Symons (1989, Nucl. Acids. Res., 15 17, 1371-1371) into two portions.

Figure 3 is a diagrammatic representation of the general structure of a hairpin ribozyme. Helix 2 (H2) is provided with a least 4 base pairs (i.e., n is 1, 2, 3 or 4) and helix 5 can be optionally provided of length 2 20 or more bases (preferably 3 - 20 bases, i.e., m is from 1 - 20 or more). Helix 2 and helix 5 may be covalently linked by one or more bases (i.e., r is ≥ 1 base). Helix 1, 4 or 5 may also be extended by 2 or more base pairs (e.g., 4 - 20 base pairs) to stabilize the ribozyme 25 structure, and preferably is a protein binding site. In each instance, each N and N' independently is any normal or modified base and each dash represents a potential base-pairing interaction. These nucleotides may be modified at the sugar, base or phosphate. Complete base- 30 pairing is not required in the helices, but is preferred. Helix 1 and 4 can be of any size (i.e., o and p is each independently from 0 to any number, e.g., 20) as long as some base-pairing is maintained. Essential bases are

shown as specific bases in the structure, but those in the art will recognize that one or more may be modified chemically (abasic, base, sugar and/or phosphate modifications) or replaced with another base without 5 significant effect. Helix 4 can be formed from two separate molecules, i.e., without a connecting loop. The connecting loop when present may be a ribonucleotide with or without modifications to its base, sugar or phosphate.

"q" is \geq 2 bases. The connecting loop can also be 10 replaced with a non-nucleotide linker molecule. H refers to bases A, U, or C. Y refers to pyrimidine bases.

" " refers to a covalent bond.

Figure 4 is a representation of the general structure of the hepatitis Δ virus ribozyme domain known 15 in the art.

Figure 5 is a representation of the general structure of the self-cleaving VS RNA ribozyme domain.

Detailed Description Of The Invention

20 The present invention concerns compositions and methods for the modulation of gene expression in plants specifically using enzymatic nucleic acid molecules.

The following phrases and terms are defined below:

25 By "inhibit" or "modulate" is meant that the activity of enzymes, such as solanidine UDP-glucose glucosyl-transferase, potato citrate synthase, or level of mRNAs encoded by these genes is reduced below that observed in the absence of an enzymatic nucleic acid and 30 preferably is below that level observed in the presence of an inactive RNA molecule able to bind to the same site on the mRNA, but unable to cleave that RNA.

By "enzymatic nucleic acid molecule" it is meant a nucleic acid molecule which has complementarity in a substrate binding region to a specified gene target, and also has an enzymatic activity which is active to 5 specifically cleave that target. That is, the enzymatic nucleic acid molecule is able to intermolecularly cleave RNA (or DNA) and thereby inactivate a target RNA molecule. This complementarity functions to allow sufficient hybridization of the enzymatic nucleic acid 10 molecule to the target RNA to allow the cleavage to occur. One hundred percent complementarity is preferred, but complementarity as low as 50-75% may also be useful in this invention. The nucleic acids may be modified at the base, sugar, and/or phosphate groups. The term 15 enzymatic nucleic acid is used interchangeably with phrases such as ribozymes, catalytic RNA, enzymatic RNA, catalytic DNA, nucleozyme, DNAzyme, RNA enzyme, RNAzyme, polyribozymes, molecular scissors, self-splicing RNA, self-cleaving RNA, cis-cleaving RNA, autolytic RNA, 20 endoribonuclease, minizyme, leadzyme, oligozyme or DNA enzyme. All of these terminologies describe nucleic acid molecules with enzymatic activity. The term encompasses enzymatic RNA molecule which include one or more ribonucleotides and may include a majority of other types 25 of nucleotides or abasic moieties, as described below.

By "complementarity" is meant a nucleic acid that can form hydrogen bond(s) with other RNA sequences by either traditional Watson-Crick or other non-traditional types (for example, Hoogsteen type) of base-paired 30 interactions.

By "vectors" is meant any nucleic acid- and/or viral-based technique used to deliver and/or express a desired nucleic acid.

By "gene" is meant a nucleic acid that encodes an RNA.

By "plant gene" is meant a gene encoded by a plant.

By "endogenous" gene is meant a gene normally found 5 in a plant cell in its natural location in the genome.

By "foreign" or "heterologous" gene is meant a gene not normally found in the host plant cell, but that is introduced by standard gene transfer techniques.

By "nucleic acid" is meant a molecule which can be 10 single-stranded or double-stranded, composed of nucleotides containing a sugar, a phosphate and either a purine or pyrimidine base which may be same or different, and may be modified or unmodified.

By "genome" is meant genetic material contained in 15 each cell of an organism and/or a virus.

By "mRNA" is meant RNA that can be translated into protein by a cell.

By "cDNA" is meant DNA that is complementary to and derived from a mRNA.

20 By "dsDNA" is meant a double stranded cDNA.

By "sense" RNA is meant RNA transcript that comprises the mRNA sequence.

By "antisense RNA" is meant an RNA transcript that comprises sequences complementary to all or part of a 25 target RNA and/or mRNA and that blocks the expression of a target gene by interfering with the processing, transport and/or translation of its primary transcript and/or mRNA. The complementarity may exist with any part of the target RNA, i.e., at the 5' non-coding 30 sequence, 3' non-coding sequence, introns, or the coding sequence. Antisense RNA is normally a mirror image of the sense RNA.

By "expression", as used herein, is meant the transcription and stable accumulation of the enzymatic

nucleic acid molecules, mRNA and/or the antisense RNA inside a plant cell. Expression of genes involves transcription of the gene and translation of the mRNA into precursor or mature proteins.

5 By "cosuppression" is meant the expression of a foreign gene, which has substantial homology to an gene, and in a plant cell causes the reduction in activity in of the foreign and/or the endogenous protein product.

10 By "altered levels" is meant the level of production of a gene product in a transgenic organism is different from that of a normal or non-transgenic organism.

By "promoter" is meant nucleotide sequence element within a gene which controls the expression of that gene.

15 Promoter sequence provides the recognition for RNA polymerase and other transcription factors required for efficient transcription. Promoters from a variety of sources can be used efficiently in plant cells to express ribozymes. For example, promoters of bacterial origin, such as the octopine synthetase promoter, the nopaline synthase promoter, the manopine synthetase promoter; promoters of viral origin, such as the cauliflower mosaic virus (35S); plant promoters, such as the ribulose-1,6-biphosphate (RUBP) carboxylase small subunit (ssu), the beta-conglycinin promoter, the phaseolin promoter, the 20 ADH promoter, heat-shock promoters, and tissue specific promoters. Promoter may also contain certain enhancer sequence elements that may improve the transcription 25 efficiency.

By "enhancer" is meant nucleotide sequence element 30 which can stimulate promoter activity (Adh).

By "constitutive promoter" is meant promoter element that directs continuous gene expression in all cells types and at all times (actin, ubiquitin, CaMV 35S).

By "tissue-specific" promoter is meant promoter element responsible for gene expression in specific cell or tissue types, such as the leaves or seeds (zein, oleosin, napin, ACP).

5 By "development-specific" promoter is meant promoter element responsible for gene expression at specific plant developmental stage, such as in early or late embryogenesis.

By "inducible promoter" is meant promoter element 10 which is responsible for expression of genes in response to a specific signal, such as: physical stimulus (heat shock genes); light (RUBP carboxylase); hormone (Em); metabolites; and stress.

By a "plant" is meant a photosynthetic organism, 15 either eukaryotic and prokaryotic.

By "angiosperm" is meant a plant having its seed enclosed in an ovary (e.g., coffee, tobacco, bean, pea).

By "gymnosperm" is meant a plant having its seed exposed and not enclosed in an ovary (e.g., pine, 20 spruce).

By "monocotyledon" is meant a plant characterized by the presence of only one seed leaf (primary leaf of the embryo). For example, maize, wheat, rice and others.

By "dicotyledon" is meant a plant producing seeds 25 with two cotyledons (primary leaf of the embryo). For example, coffee, canola, peas and others.

By "transgenic plant" is meant a plant expressing a foreign gene.

By "open reading frame" is meant a nucleotide 30 sequence, without introns, encoding an amino acid sequence, with a defined translation initiation and termination region.

The invention provides a method for producing a class of enzymatic cleaving agents which exhibit a high

degree of specificity for the RNA of a desired target. The enzymatic nucleic acid molecule may be targeted to a highly specific sequence region of a target such that specific gene inhibition can be achieved. Alternatively, 5 enzymatic nucleic acid can be targeted to a highly conserved region of a gene family to inhibit gene expression of a family of related enzymes. The ribozymes can be expressed in plants that have been transformed with vectors which express the nucleic acid of the 10 present invention.

The enzymatic nature of a ribozyme is advantageous over other technologies, since the concentration of ribozyme necessary to affect a therapeutic treatment is lower. This advantage reflects the ability of the 15 ribozyme to act enzymatically. Thus, a single ribozyme molecule is able to cleave many molecules of target RNA.

In addition, the ribozyme is a highly specific inhibitor, with the specificity of inhibition depending not only on the base-pairing mechanism of binding to the 20 target RNA, but also on the mechanism of target RNA cleavage. Single mismatches, or base-substitutions, near the site of cleavage can completely eliminate catalytic activity of a ribozyme.

Seven basic varieties of naturally-occurring 25 enzymatic RNAs are known presently. Each can catalyze the hydrolysis of RNA phosphodiester bonds in trans (and thus can cleave other RNA molecules) under physiological conditions. Table I summarizes some of the characteristics of these ribozymes. In general, enzymatic nucleic 30 acids act by first binding to a target RNA. Such binding occurs through the target binding portion of an enzymatic nucleic acid which is held in close proximity to an enzymatic portion of the molecule that acts to cleave the target RNA. Thus, the enzymatic nucleic acid first

recognizes and then binds a target RNA through complementary base-pairing, and once bound to the correct site, acts enzymatically to cut the target RNA. Strategic cleavage of such a target RNA will destroy its 5 ability to direct synthesis of an encoded protein. After an enzymatic nucleic acid has bound and cleaved its RNA target, it is released from that RNA to search for another target and can repeatedly bind and cleave new targets.

10 In one of the preferred embodiments of the inventions herein, the enzymatic nucleic acid molecule is formed in a hammerhead or hairpin motif, but may also be formed in the motif of a hepatitis Δ virus, group I intron, group II intron or RNaseP RNA (in association 15 with an RNA guide sequence) or Neurospora VS RNA. Examples of such hammerhead motifs are described by Dreyfus, supra, Rossi et al., 1992, AIDS Research and Human Retroviruses 8, 183; of hairpin motifs by Hampel et al., EP0360257, Hampel and Tritz, 1989 Biochemistry 28, 20 4929, Feldstein et al., 1989, Gene 82, 53, Haseloff and Gerlach, 1989, Gene, 82, 43, and Hampel et al., 1990 Nucleic Acids Res. 18, 299; of the hepatitis Δ virus motif is described by Perrotta and Been, 1992 Biochemistry 31, 16; of the RNaseP motif by Guerrier- 25 Takada et al., 1983 Cell 35, 849; Forster and Altman, 1990, Science 249, 783; Li and Altman, 1996, Nucleic Acids Res. 24, 835; Neurospora VS RNA ribozyme motif is described by Collins (Saville and Collins, 1990 Cell 61, 685-696; Saville and Collins, 1991 Proc. Natl. Acad. Sci. 30 USA 88, 8826-8830; Collins and Olive, 1993 Biochemistry 32, 2795-2799; Guo and Collins, 1995, EMBO. J. 14, 363); Group II introns are described by Griffin et al., 1995, Chem. Biol. 2, 761; Michels and Pyle, 1995, Biochemistry

34, 2965; and of the Group I intron by Cech et al., U.S. Patent 4,987,071. These specific motifs are not limiting in the invention and those skilled in the art will recognize that all that is important in an enzymatic 5 nucleic acid molecule of this invention is that it has a specific substrate binding site which is complementary to one or more of the target gene RNA regions, and that it have nucleotide sequences within or surrounding that substrate binding site which impart an RNA cleaving 10 activity to the molecule.

The enzymatic nucleic acid molecules of the instant invention will be expressed within cells from eukaryotic promoters [e.g., Gerlach et al., International PCT Publication No. WO 91/13994; Edington and Nelson, 1992, 15 in Gene Regulation: Biology of Antisense RNA and DNA, eds. R. P. Erickson and J. G. Izant, pp 209-221, Raven Press, NY.; Atkins et al., International PCT Publication No. WO 94/00012; Lenee et al., International PCT Publication Nos. WO 94/19476 and WO 9503404, Atkins et 20 al., 1995, J. Gen. Virol. 76, 1781-1790; McElroy and Brettell, 1994, TIBTECH 12, 62; Gruber et al., 1994, J. Cell. Biochem. Suppl. 18A, 110 (X1-406) and Feyter et al., 1996, Mol. Gen. Genet. 250, 329-338; all of these are incorporated by reference herein]. Those skilled in the 25 art will realize from the teachings herein that any ribozyme can be expressed in eukaryotic plant cells from an appropriate promoter. The ribozymes expression is under the control of a constitutive promoter, a tissue-specific promoter or an inducible promoter.

30 To obtain the ribozyme mediated modulation, the ribozyme RNA is introduced into the plant. There are also numerous ways to transform plants; plants can be transformed using the gene gun (US Patents 4,945,050 to Cornell and 5,141,131 to DowElanco); plants may be

transformed using Agrobacterium technology, see US Patent 5,177,010 to University of Toledo, 5,104,310 to Texas A&M, European Patent Application 0131624B1, European Patent Applications 120516, 159418B1 and 176,112 to 5 Schilperoot, US Patents 5,149,645, 5,469,976, 5,464,763 and 4,940,838 and 4,693,976 to Schilperoot, European Patent Applications 116718, 290799, 320500 all to MaxPlanck, European Patent Applications 604662 and 627752 to Japan Tobacco, European Patent Applications 10 0267159, and 0292435 and US Patent 5,231,019 all to Ciba Geigy, US Patents 5,463,174 and 4,762,785 both to Calgene, and US Patents 5,004,863 and 5,159,135 both to Agracetus; whiskers technology, see US Patents 5,302,523 and 5,464,765 both to Zeneca; electroporation technology, 15 see WO 87/06614 to Boyce Thompson Institute, 5,472,869 and 5,384,253 both to Dekalb, WO9209696 and WO9321335 both to PGS; all of which are incorporated by reference herein in totality. In addition to numerous technologies for transforming plants, the type of tissue which is 20 contacted with the foreign material (typically plasmids containing RNA or DNA) may vary as well. Such tissue would include but would not be limited to embryogenic tissue, callus tissue type I and II, and any tissue which is receptive to transformation and subsequent 25 regeneration into a transgenic plant. Another variable is the choice of a selectable marker. The preference for a particular marker is at the discretion of the artisan, but any of the following selectable markers may be used along with any other gene not listed herein which could 30 function as a selectable marker. Such selectable markers include but are not limited to chlorosulfuron, hygromycin, PAT and/or bar, bromoxynil, kanamycin and the like. The bar gene may be isolated from Strptomuces, particularly from the hygroscopicus or viridochromogenes

species. The bar gene codes for phosphinothricin acetyl transferase (PAT) that inactivates the active ingradient in the herbicide bialaphos phosphinothricin (PPT). Thus, numerous combinations of technologies may be used in 5 employing ribozyme mediated modulation.

The ribozymes may be expressed individually as monomers, i.e., one ribozyme targeted against one site is expressed per transcript. Alternatively, two or more ribozymes targeted against more than one target site are 10 expressed as part of a single RNA transcript. A single RNA transcript comprising more than one ribozyme targeted against more than one cleavage site are readily generated to achieve efficient modulation of gene expression.

Ribozymes within these multimer constructs are the same 15 or different. For example, the multimer construct may comprise a plurality of hammerhead ribozymes or hairpin ribozymes or other ribozyme motifs. Alternatively, the multimer construct may be designed to include a plurality of different ribozyme motifs, such as hammerhead and 20 hairpin ribozymes. More specifically, multimer ribozyme constructs are designed, wherein a series of ribozyme motifs are linked together in tandem in a single RNA transcript. The ribozymes are linked to each other by nucleotide linker sequence, wherein the linker sequence 25 may or may not be complementary to the target RNA. Multimer ribozyme constructs (polyribozymes) are likely to improve the effectiveness of ribozyme-mediated modulation of gene expression.

The activity of ribozymes can also be augmented by 30 their release from the primary transcript by a second ribozyme (Draper et al., PCT WO 93/23569, and Sullivan et al., PCT WO 94/02595, both hereby incorporated in their totality by reference herein; Ohkawa, J., et al., 1992, Nucleic Acids Symp. Ser., 27, 15-6; Taira, K., et al.,

1991, Nucleic Acids Res., 19, 5125-30; Ventura, M., et al., 1993, Nucleic Acids Res., 21, 3249-55; Chowrira et al., 1994 J. Biol. Chem. 269, 25856).

Ribozyme-mediated modulation of gene expression can 5 be practiced in a wide variety of plants including but not limited to potato, lettuce, spinach, cabbage, brussel sprouts, arugula, kale, collards, chard, beet, turnip, sweet potato and turfgrass. Following are a few non-limiting examples that describe the general utility of 10 ribozymes in modulation of gene expression.

Thus, in one instance, the invention concerns compositions (and methods for their use) for the modulation of genes involved in the biosynthesis of undesirable alkaloid compounds in plants. This is 15 accomplished through the inhibition of genetic expression, with ribozymes, which results in the reduction or elimination of certain gene activities in plants, such as solanidine UDP-glucose glucosyl-transferase. Such activity is reduced in plants, such as potato and other 20 solanaceous plants. These endogenously expressed ribozyme molecules contain substrate binding domains that bind to accessible regions of the target RNA. The RNA molecules also contain domains that catalyze the cleavage 25 of RNA. The RNA molecules are preferably ribozymes of the hammerhead or hairpin motif. Upon binding, the ribozymes cleave the target mRNAs, preventing translation and protein accumulation. In the absence of the expression of the target gene, and/or if the level of expression of the target gene is significantly reduced, 30 levels of undesirable alkaloids is reduced or inhibited.

Specific examples are provided below in the Tables III and IV.

In one aspect, the ribozymes have binding arms which are complementary to the substrate sequences in Tables

III and IV. Those in the art will recognize that while such examples are designed to one gene RNA (solanidine UDP-glucose glucosyl-transferase) of one plant(e.g., potato), similar ribozymes can be made complementary to 5 other genes in other plant's RNA. By complementary is thus meant that the binding arms of the ribozymes are able to interact with the target RNA in a sequence-specific manner and enable the ribozyme to cause cleavage of a plant mRNA target. Examples of such ribozymes are 10 typically sequences defined in Tables III and IV. The active ribozyme typically contains an enzymatic center equivalent to those in the examples, and binding arms able to bind plant mRNA such that cleavage at the target site occurs. Other sequences may be present which do not 15 interfere with such binding and/or cleavage.

In another instance, the invention features compositions (and methods for their use) for the modulation of genes involved in the flower formation in plants. This is accomplished through the inhibition of 20 genetic expression, with ribozymes, which results in the reduction or elimination of certain gene activities in plants, such as citrate synthase. Such activity can be reduced in plants, such as lettuce, spinach, cabbage, brussel sprouts, arugula, kale, collards, chard, beet, 25 turnip, potato, sweet potato and turfgrass. These endogenously expressed ribozyme molecules contain substrate binding domains that bind to accessible regions of the target RNA. The RNA molecules also contain domains that catalyze the cleavage of RNA. The RNA molecules are 30 preferably ribozymes of the hammerhead or hairpin motif.

Upon binding, the ribozymes cleave the target mRNAs, preventing translation and protein accumulation. In the absence of the expression of the target gene, and/or if the level of expression of the target gene is

significantly reduced, levels of undesirable alkaloids is reduced or inhibited. Specific examples are provided below in the Tables V and VI. In a non-limiting example, ribozymes have binding arms which are complementary to 5 the substrate sequences shown in Tables V and VI are disclosed. Those in the art will recognize that while such examples are designed to one gene RNA (citrate synthase) of one plant (e.g., potato), similar ribozymes can be made complementary to other genes in other plant's 10 RNA. By complementary is thus meant that the binding arms of the ribozymes are able to interact with the target RNA in a sequence-specific manner and enable the ribozyme to cause cleavage of a plant mRNA target. Examples of such ribozymes are typically sequences 15 defined in Tables V and VI. The active ribozyme typically contains an enzymatic center equivalent to those in the examples, and binding arms able to bind plant mRNA such that cleavage at the target site occurs. Other sequences may be present which do not interfere with such binding 20 and/or cleavage.

The sequences of the ribozymes that are particularly useful in this study, are shown in Tables III-VI.

Those in the art will recognize that ribozyme sequences listed in the Tables are representative only of 25 many more such sequences where the enzymatic portion of the ribozyme (all but the binding arms) is altered to affect activity. For example, stem-loop II sequence of hammerhead ribozymes listed in Table III and V (5'-GGCGAAAGCC-3') can be altered (substitution, deletion, 30 and/or insertion) to contain any sequences, preferably provided that a minimum of a two base-paired stem structure can form. Similarly, stem-loop IV sequence of hairpin ribozymes listed in Table IV and VI (5'-CACGUUGUG-3') can be altered (substitution, deletion,

and/or insertion) to contain any sequence, preferably provided that a minimum of a two base-paired stem structure can form. Such ribozymes are equivalent to the ribozymes described specifically in the Tables.

5 Preferably, the recombinant vectors capable of stable integration into the plant genome and selection of transformed plant lines expressing the ribozymes are expressed either by constitutive or inducible promoters in the plant cells. Once expressed, the ribozymes cleave
10 their target mRNAs and reduce alkaloid production in their host cells. The ribozymes expressed in plant cells are under the control of a constitutive promoter, a tissue-specific promoter or an inducible promoter.

Modification of undesirable alkaloid profile is an
15 important application of nucleic acid-based technologies which are capable of reducing specific gene expression. A high level of undesirable alkaloid compounds is undesirable in plants that produce products of commercial importance.

20 In preferred embodiments, hairpin and hammerhead ribozymes that cleave solanidine UDP-glucose glucosyl-transferase RNA are described. Those of ordinary skill in the art will understand from the examples described below that other ribozymes that cleave target RNAs
25 required for solanidine UDP-glucose glucosyl-transferase activity may now be readily designed and are within the scope of the invention.

Modification of flower formation is an important application of nucleic acid-based technologies which are
30 capable of reducing specific gene expression. In preferred embodiments, hairpin and hammerhead ribozymes that cleave potato citrate synthase RNA are described. Those of ordinary skill in the art will understand from the examples described below that other ribozymes that

cleave target RNAs required for potato citrate synthase activity may now be readily designed and are within the scope of the invention

While specific examples to potato RNA are provided, 5 those in the art will recognize that the teachings are not limited to potato. Furthermore, the same or equivalent target may be used in other plant species. The complementary arms suitable for targeting the specific plant RNA sequences are utilized in the ribozyme 10 targeted to that specific RNA. The examples and teachings herein are meant to be non-limiting, and those skilled in the art will recognize that similar embodiments can be readily generated in a variety of different plants to modulate expression of a variety of different genes, 15 using the teachings herein, and are within the scope of the inventions.

Standard molecular biology techniques were followed in the examples herein. Additional information may be found in Sambrook, J., Fritsch, E. F., and Maniatis, T. 20 (1989), Molecular Cloning a Laboratory Manual, second edition, Cold Spring Harbor: Cold Spring Harbor Laboratory Press, which is incorporated herein by reference.

25 Examples

Example 1: Identification of Potential Ribozyme Cleavage
Sites for solanidine UDP-glucose glucosyl-transferase

Approximately 353 HH ribozyme cleavage sites and approximately 20 HP sites were identified in the potato 30 solanidine UDP-glucose glucosyl-transferase RNA. A HH site consists of a uridine and any nucleotide except guanosine (UH). Tables III and IV have a list of HH and HP ribozyme cleavage sites. The numbering system starts with 1 at the 5' end of a solanidine UDP-glucose

glucosyl-transferase RNA having the sequence shown in Moehs et al., supra.

Ribozymes, such as those listed in Tables III and IV, can be readily designed and synthesized to such 5 cleavage sites with between 5 and 100 or more bases as substrate binding arms (see Figs. 1 - 5). These substrate binding arms within a ribozyme allow the ribozyme to interact with their target in a sequence-specific manner.

10

Example 2: Selection of Ribozyme Cleavage Sites for solanidine UDP-glucose glucosyl-transferase

The secondary structure of solanidine UDP-glucose glucosyl-transferase RNA was assessed by computer 15 analysis using algorithms, such as those developed by M. Zuker (Zuker, M., 1989 Science, 244, 48-52). Regions of the mRNA that did not form secondary folding structures with RNA/RNA stems of over eight nucleotides and contained potential hammerhead ribozyme cleavage sites 20 were identified.

Example 3: Hammerhead and Hairpin Ribozymes for solanidine UDP-glucose glucosyl-transferase

Hammerhead (HH) and hairpin (HP) ribozymes are 25 subjected to analysis by computer folding and the ribozymes that had significant secondary structure are rejected.

The ribozymes are chemically synthesized. The general procedures for RNA synthesis have been described 30 previously (Usman et al., 1987, J. Am. Chem. Soc., 109, 7845-7854 and in Scaringe et al., 1990, Nucl. Acids Res., 18, 5433-5341; Wincott et al., 1995, Nucleic Acids Res. 23, 2677). Small scale syntheses are conducted on a 394 Applied Biosystems, Inc. synthesizer using a modified 2.5

μmol scale protocol with a 5 min coupling step for alkylsilyl protected nucleotides and 2.5 min coupling step for 2'-O-methylated nucleotides. Table II outlines the amounts, and the contact times, of the reagents used 5 in the synthesis cycle. A 6.5-fold excess (163 μL of 0.1 M = 16.3 μmol) of phosphoramidite and a 24-fold excess of S-ethyl tetrazole (238 μL of 0.25 M = 59.5 μmol) relative to polymer-bound 5'-hydroxyl was used in each coupling cycle. Average coupling yields on the 394, determined by 10 colorimetric quantitation of the trityl fractions, was 97.5-99%. Other oligonucleotide synthesis reagents for the 394: Detritylation solution was 2% TCA in methylene chloride (ABI); capping was performed with 16% N-Methyl imidazole in THF (ABI) and 10% acetic anhydride/10% 2,6-lutidine in THF (ABI); oxidation solution is 16.9 mM I₂, 15 49 mM pyridine, 9% water in THF (Millipore). B & J Synthesis Grade acetonitrile is used directly from the reagent bottle. S-Ethyl tetrazole solution (0.25 M in acetonitrile) was made up from the solid obtained from 20 American International Chemical, Inc.

Deprotection of the RNA is performed as follows. The polymer-bound oligoribonucleotide, trityl-off, is transferred from the synthesis column to a 4 mL glass screw top vial and suspended in a solution of methylamine 25 (MA) at 65°C for 10 min. After cooling to -20°C, the supernatant is removed from the polymer support. The support is washed three times with 1.0 mL of EtOH:MeCN:H₂O/3:1:1, vortexed and the supernatant is then added to the first supernatant. The combined supernatants, containing the oligoribonucleotide, are dried to 30 a white powder.

The base-deprotected oligoribonucleotide is resuspended in anhydrous TEA•HF/NMP solution (250 μL of a

solution of 1.5 mL N-methylpyrrolidinone, 750 μ L TEA and 1.0 mL TEA•3HF to provide a 1.4 M HF concentration) and heated to 65°C for 1.5 h. The resulting, fully deprotected, oligomer is quenched with 50 mM TEAB (9 mL) 5 prior to anion exchange desalting.

For anion exchange desalting of the deprotected oligomer, the TEAB solution is loaded onto a Qiagen 500[®] anion exchange cartridge (Qiagen Inc.) that is prewashed with 50 mM TEAB (10 mL). After washing the loaded 10 cartridge with 50 mM TEAB (10 mL), the RNA is eluted with 2 M TEAB (10 mL) and dried down to a white powder.

Inactive hammerhead ribozymes are synthesized by substituting a U for G₅ and a U for A₁₄ (numbering from (Hertel, K. J., et al., 1992, Nucleic Acids Res., 20, 15 3252).

The hairpin ribozymes are synthesized as described above for the hammerhead RNAs.

Ribozymes can also be synthesized from DNA templates using bacteriophage T7 RNA polymerase (Milligan 20 and Uhlenbeck, 1989, Methods Enzymol. 180, 51).

Ribozymes are purified by gel electrophoresis using general methods or are purified by high pressure liquid chromatography (HPLC; See Wincott et al., 1996, supra, the totality of which is hereby incorporated herein by 25 reference) and were resuspended in water. The sequences of the chemically synthesized ribozymes used in this study are shown below in Tables III and IV.

Example 4: Construction of Ribozyme expressing 30 transcription units for solanidine UDP-glucose glucosyl-transferase

Ribozymes targeted to cleave solanidine UDP-glucose glucosyl-transferase RNA can be endogenously expressed in

plants, either from genes inserted into the plant genome (stable transformation) or from episomal transcription units (transient expression) which are part of plasmid vectors or viral sequences. These ribozymes can be 5 expressed via RNA polymerase I, II, or III plant or plant virus promoters (such as CaMV). Promoters can be either constitutive, tissue specific, or developmentally expressed.

10 Example 5: Identification of Potential Ribozyme Cleavage Sites for potato citrate synthase

Approximately 398 HH ribozyme cleavage sites and approximately 25 HP sites were identified in the potato citrate synthase RNA. A HH site consists of a uridine 15 and any nucleotide except guanosine (UH). Tables V and VI have a list of HH and HP ribozyme cleavage sites.

Ribozymes, such as those listed in Tables III and IV, can be readily designed and synthesized to such cleavage sites with between 5 and 100 or more bases as 20 substrate binding arms (see Figs. 1 - 5). These substrate binding arms within a ribozyme allow the ribozyme to interact with their target in a sequence-specific manner.

25 Example 6: Selection of Ribozyme Cleavage Sites for potato citrate synthase

The secondary structure of potato citrate synthase RNA was assessed by computer analysis using algorithms, such as those developed by M. Zuker (Zuker, M., 1989 30 Science, 244, 48-52). Regions of the mRNA that did not form secondary folding structures with RNA/RNA stems of over eight nucleotides and contained potential hammerhead ribozyme cleavage sites were identified.

Example 7: Hammerhead and Hairpin Ribozymes for potato citrate synthase

Hammerhead (HH) and hairpin (HP) ribozymes are subjected to analysis by computer folding and the 5 ribozymes that had significant secondary structure are rejected.

The ribozymes are synthesized as described above. The sequences of the chemically synthesized ribozymes used in this study are shown below in Tables V and VI.

10

Example 8: Construction of Ribozyme expressing transcription units for potato citrate synthase

Ribozymes targeted to cleave potato citrate synthase RNA can be endogenously expressed in plants, 15 either from genes inserted into the plant genome (stable transformation) or from episomal transcription units (transient expression) which are part of plasmid vectors or viral sequences. These ribozymes can be expressed via RNA polymerase I, II, or III plant or plant virus 20 promoters (such as CaMV). Promoters can be either constitutive, tissue specific, or developmentally expressed.

25

Example 9: Plant Transformation and Construction

There are several methods to genetically engineer plants (for a review see Gasser et al., 1989 Science 244, 1293-1299; Potrykus, 1991 Annu. Rev. Plant Physiol. Plant Mol. Biol. 42, 205-225; Gasser and Fraley, 1992 30 Scientific American June 1992 pp 62-69). These methods can be used to introduce the above ribozymes directly or via expression vectors. These methods include the following:

Helium blasting involves accelerating suspended DNA-coated gold particles towards and into prepared tissue targets. The device used was an earlier prototype to the one described in a DowElanco U.S. Patent (#5,141,131) 5 which is incorporated herein by reference, although both function in a similar manner. The device consists of a high pressure helium source, a syringe containing the DNA/gold suspension, and a pneumatically-operated multipurpose valve which provides controlled linkage 10 between the helium source and a loop of pre-loaded DNA/gold suspension. Prior to blasting, tissue targets are covered with a sterile 104 micron stainless steel screen, which holds the tissue in place during impact. Next, targets are placed under vacuum in the main chamber 15 of the device. The DNA-coated gold particles are accelerated at the target 4 times using a helium pressure of 1500 psi. Each blast delivered 20 μ l of DNA/gold suspension. Immediately post-blasting, the targets are placed back on maintenance medium plus osmoticum for a 16 20 to 24 hour recovery period.

Particle Bombardment-mediated transformation
(Gordon-Kamm et al., 1990 The Plant Cell 2, 603-618; Potrykus, 1991 Annu. Rev. Plant Physiol. Plant Mol. Biol. 42, 205-225; Gasser and Fraley, 1992 Scientific American 25 June 1992 pp 62-69; Vain et al., 1993 Plant Cell Rep. 12, 84-88; Weymann et al., 1993 In Vitro Cell. Dev. Biol. 29P, 33-37): This strategy involves bombardment of plant cells with minute (1-2 microns in diameter) metal particles (for example tungsten or gold particles) using 30 a "gene" gun (also referred to as "Biolistics" or "particle" gun). The metal particles, coated with genetic material (ribozyme or ribozyme encoding plasmids), can penetrate the cell wall, without causing

any irreversible damage to the cell, and deliver the genetic material to the cytoplasm.

5 Electroporation-mediated transformation (Fromm et al., 1986 Nature 319, 791-793; Rhodes et al., 1988 Science 240, 204-207; Potrykus, 1991 Annu. Rev. Plant Physiol. Plant Mol. Biol. 42, 205-225; Gasser and Fraley, 1992 Scientific American June 1992 pp 62-69; D'Halluin et al., 1992 The Plant Cell 4, 1495-1505; Sukhapinda et al., 1993 Plant Cell Rep. 13, 63-68; Laursen et al., 1994 Plant Mol. Biol. 24, 51-61): This technique involves permeabilizing the target cell membrane by using short high voltage electric pulses. Nucleic acids (ribozyme encoding plasmids) can pass through a permeabilized cell membrane and potentially integrate into the host genome 10 resulting in a transformed phenotype. Electroporation can be carried out on (a) plant protoplasts, plant cells lacking a cell wall, (Fromm et al., 1986 Nature 319, 791-793; Rhodes et al., 1988 Science 240, 204-207; Sukhapinda et al., 1993 Plant Cell Rep. 13, 63-68); (b) cultured 15 cells (Laursen et al., 1994 Plant Mol. Biol. 24, 51-61); (c) Plant tissue (D'Halluin et al., 1992 The Plant Cell 4, 1495-1505).

20 Agrobacterium-mediated transformation: This method uses a disarmed (disease causing genes are deleted) 25 species of Agrobacterium tumefaciens or Agrobacterium rizogenes (Potrykus, 1991 Annu. Rev. Plant Physiol. Plant Mol. Biol. 42, 205-225; Gasser and Fraley, 1992 Scientific American June 1992 pp 62-69). This organism transfers part of its DNA into plant cells (T-DNA). 30 Ribozyme genes can be cloned into T-DNA fragments and Agrobacterium containing the recombinant T-DNA can be generated. Agrobacterium will infect and release the recombinant T- DNA into maize cells. The integration of

T-DNA into host DNA will result in a transformed phenotype.

Other Uses:

5 Potential usefulness of sequence-specific enzymatic nucleic acid molecules of the instant invention might have many of the same applications for the study of RNA that DNA restriction endonucleases have for the study of DNA (Nathans, D. and Smith, H. O., (1975) Ann. Rev. 10 Biochem. 44:273). For example, the pattern of restriction fragments could be used to establish sequence relationships between two related plant RNAs, and large plant RNAs could be specifically cleaved to fragments of a size more useful for study. The ability to engineer 15 sequence specificity of the ribozyme is ideal for cleavage of RNAs of unknown sequence.

Ribozymes of this invention may be used as tools to examine genetic drift and mutations within plant cells. The close relationship between ribozyme activity and the 20 structure of the target RNA allows the detection of mutations in any region of the molecule which alters the base-pairing and three-dimensional structure of the target RNA. By using multiple ribozymes described in this invention, one may map nucleotide changes which are 25 important to RNA structure and function in vitro, as well as in cells and tissues. Cleavage of target RNAs with ribozymes may be used to inhibit gene expression and define the role (essentially) of specified gene products in the synthesis of undesirable alkaloids in plants. In 30 this manner, other genetic targets may be defined as important mediators of alkaloid production. These experiments will lead to better modifications of the alkaloid production by affording the possibility of combinational concepts (e.g., multiple ribozymes targeted

to different genes intermittent treatment with combinations of ribozymes and/or other chemical or biological molecules). Other in vitro uses of ribozymes of this invention are well known in the art, and include 5 detection of the presence of mRNA associated with undesirable alkaloid production condition. Such RNA is detected by determining the presence of a cleavage product after treatment with a ribozyme using standard methodology.

10 Other embodiments are within the following claims.

Table I

Table I:Characteristics of naturally occurring ribozymesGroup I Introns

5 • Size: ~150 to >1000 nucleotides.

• Requires a U in the target sequence immediately 5' of the cleavage site.

• Binds 4-6 nucleotides at the 5'-side of the cleavage site.

10 • Reaction mechanism: attack by the 3'-OH of guanosine to generate cleavage products with 3'-OH and 5'-guanosine.

• Additional protein cofactors required in some cases to help folding and maintainance of the active structure

15 [1].

• Over 300 known members of this class. Found as an intervening sequence in *Tetrahymena thermophila* rRNA, fungal mitochondria, chloroplasts, phage T4, blue-green algae, and others.

20 • Major structural features largely established through phylogenetic comparisons, mutagenesis, and biochemical studies [2,3].

• Complete kinetic framework established for one ribozyme [4,5,6,7]

25 • Studies of ribozyme folding and substrate docking underway [8,9,10].

• Chemical modification investigation of important residues well established [11,12].

• The small (4-6 nt) binding site may make this ribozyme

30 too non-specific for targeted RNA cleavage, however, the *Tetrahymena* group I intron has been used to repair a "defective" β -galactosidase message by the ligation

Table I

of new β -galactosidase sequences onto the defective message [13].

RNase P RNA (M1 RNA)

5 • Size: ~290 to 400 nucleotides.

• RNA portion of a ubiquitous ribonucleoprotein enzyme.

• Cleaves tRNA precursors to form mature tRNA [14].

• Reaction mechanism: possible attack by M^{2+} -OH to generate cleavage products with 3'OH and 5'-phosphate.

10 • RNase P is found throughout the prokaryotes and eukaryotes. The RNA subunit has been sequenced from bacteria, yeast, rodents, and primates.

• Recruitment of endogenous RNase P for therapeutic applications is possible through hybridization of an

15 External Guide Sequence (EGS) to the target RNA

• Important phosphate and 2' OH contacts recently identified [17,18]

Group II Introns

20 • Size: >1000 nucleotides.

• Trans cleavage of target RNAs recently demonstrated [19,20].

• Sequence requirements not fully determined.

• Reaction mechanism: 2'-OH of an internal adenosine generates cleavage products with 3'-OH and a "lariat" RNA containing a 3'-5' and a 2'-5' branch point.

25 • Only natural ribozyme with demonstrated participation in DNA cleavage [21,22] in addition to RNA cleavage and ligation.

30 • Major structural features largely established through phylogenetic comparisons [23].

Table I

- Important 2' OH contacts beginning to be identified [24]
- Kinetic framework under development [25]

5 Neurospora VS RNA

- Size: ~144 nucleotides.
- Trans cleavage of hairpin target RNAs recently demonstrated [26]
- Sequence requirements not fully determined.
- 10 • Reaction mechanism: attack by 2'-OH 5' to the scissile bond to generate cleavage products with 2',3'-cyclic phosphate and 5'-OH ends.
- Binding sites and structural requirements not fully determined.
- 15 • Only 1 known member of this class. Found in Neurospora VS RNA.

Hammerhead Ribozyme

(see text for references)

- 20 • Size: ~13 to 40 nucleotides.
- Requires the target sequence UH immediately 5' of the cleavage site.
- Binds a variable number nucleotides on both sides of the cleavage site.
- 25 • Reaction mechanism: attack by 2'-OH 5' to the scissile bond to generate cleavage products with 2',3'-cyclic phosphate and 5'-OH ends.
- 14 known members of this class. Found in a number of plant pathogens (virusoids) that use RNA as the
- 30 infectious agent.
- Essential structural features largely defined, including 2 crystal structures []

Table I

- Minimal ligation activity demonstrated (for engineering through in vitro selection) []
- Complete kinetic framework established for two or more ribozymes [].
- 5 • Chemical modification investigation of important residues well established [].

Hairpin Ribozyme

- Size: ~50 nucleotides.
- 10 • Requires the target sequence GUC immediately 3' of the cleavage site.
- Binds 4-6 nucleotides at the 5'-side of the cleavage site and a variable number to the 3'- side of the cleavage site.
- 15 • Reaction mechanism: attack by 2'-OH 5' to the scissile bond to generate cleavage products with 2',3'-cyclic phosphate and 5'-OH ends.
- 3 known members of this class. Found in three plant pathogen (satellite RNAs of the tobacco ringspot virus, arabis mosaic virus and chicory yellow mottle virus) which uses RNA as the infectious agent.
- 20 • Essential structural features largely defined [27,28,29,30]
- Ligation activity (in addition to cleavage activity) makes ribozyme amenable to engineering through in vitro selection [31]
- 25 • Complete kinetic framework established for one ribozyme [31].
- Chemical modification investigation of important residues begun [33,34]

Table I

Hepatitis Delta Virus (HDV) Ribozyme

- Size: ~60 nucleotides.
- Trans cleavage of target RNAs demonstrated [31].
- Binding sites and structural requirements not fully determined, although no sequences 5' of cleavage site are required. Folded ribozyme contains a pseudoknot structure [36].
- Reaction mechanism: attack by 2'-OH 5' to the scissile bond to generate cleavage products with 2,3'-cyclic phosphate and 5'-OH ends.
- Only 2 known members of this class. Found in human HDV.
- Circular form of HDV is active and shows increased nuclease stability [37]

Claims

1. An enzymatic nucleic acid molecule with RNA cleaving activity, wherein said nucleic acid molecule modulates the expression of a plant gene involved in the 5 biosynthesis of alkaloid compounds.

2. The enzymatic nucleic acid molecule of claim 1, wherein said plant is a solanaceous plant.

10 3. The enzymatic nucleic acid molecule of claim 2, wherein said plant is selected from a group consisting of potato, tomato, pepper, eggplant and ditura.

15 4. The enzymatic nucleic acid molecule of claim 1, wherein said nucleic acid is in a hammerhead configuration.

20 5. The enzymatic nucleic acid molecule of claim 1, wherein said nucleic acid is in a hairpin configuration.

25 6. The enzymatic nucleic acid molecule of claim 1, wherein said nucleic acid is in a hepatitis δ virus, group I intron, group II intron, VS nucleic acid or RNaseP nucleic acid configuration.

7. The enzymatic nucleic acid of claim 1, wherein said nucleic acid comprises between 12 and 100 bases complementary to RNA of said gene.

30

8. The enzymatic nucleic acid of claim 1, wherein said nucleic acid comprises between 14 and 24 bases complementary to RNA of said gene.

9. The enzymatic nucleic acid of claim 4, wherein said hammerhead comprises a stem II region of length greater than or equal to two base-pairs.

5 10. The enzymatic nucleic acid of claim 5, wherein said hairpin comprises a stem II region of length between three and seven base-pairs.

10 11. The enzymatic nucleic acid of claim 5, wherein said hairpin comprises a stem IV region of length greater than or equal to two base-pairs.

12. The enzymatic nucleic acid of claim 1, wherein said gene is solanidine UDP-glucose glucosyl-transferase.

15 13. The enzymatic nucleic acid molecule of claim 12, wherein said nucleic acid specifically cleaves any of sequences shown in Table III, wherein said nucleic acid is in a hammerhead configuration.

20 14. The enzymatic nucleic acid molecule of claim 12, wherein said nucleic acid specifically cleaves any of sequences shown in Table IV, wherein said nucleic acid is in a hairpin configuration.

25 15. The enzymatic nucleic acid molecule of any of claims 13 or 14, consisting essentially of one or more sequences selected from the group shown in Tables III and IV.

30 16. A plant cell comprising the enzymatic nucleic acid molecule of claim 1.

17. A transgenic plant and the progeny thereof, comprising the enzymatic nucleic acid molecule of claim 1.

5 18. An expression vector comprising nucleic acid encoding the enzymatic nucleic acid molecule of claim 1, in a manner which allows expression and/or delivery of that enzymatic nucleic acid molecule within a plant cell.

10 19. An expression vector comprising nucleic acid encoding a plurality of enzymatic nucleic acid molecules of claim 1, in a manner which allows expression and/or delivery of said enzymatic nucleic acid molecules within a plant cell.

15 20. A plant cell comprising the expression vector of claim 18.

21. A plant cell comprising the expression vector
20 of claim 19.

22. A transgenic plant and the progeny thereof, comprising the expression vector of claim 18.

25 23. A transgenic plant and the progeny thereof, comprising the expression vector of claim 19.

24. A method for modulating expression of an gene in a plant by administering to said plant the enzymatic
30 nucleic acid molecule of claim 1.

25. The method of claim 24, wherein said plant is a potato plant.

26. The method of claim 24, wherein said gene is solanidine UDP-glucose glucosyl-transferase.

27. The expression vector of claim 18, wherein 5 said vector comprises:

- a) a transcription initiation region;
- b) a transcription termination region;
- c) a gene encoding at least one said enzymatic nucleic acid molecule; and

10 wherein said gene is operably linked to said initiation region and said termination region, in a manner which allows expression and/or delivery of said enzymatic molecule within said plant cell.

15 28. The expression vector of claim 18, wherein said vector comprises:

- a) a transcription initiation region;
- b) a transcription termination region;
- c) an open reading frame;

20 d) a gene encoding at least one said enzymatic nucleic acid molecule, wherein said gene is operably linked to the 3'-end of said open reading frame; and

25 wherein said gene is operably linked to said initiation region, said open reading frame and said termination region, in a manner which allows expression and/or delivery of said enzymatic molecule within said plant cell.

29. The expression vector of claim 18, wherein 30 said vector comprises:

- a) a transcription initiation region;
- b) a transcription termination region;
- c) an intron;

d) a gene encoding at least one said enzymatic nucleic acid molecule; and

wherein said gene is operably linked to said initiation region, said intron and said termination region, in a manner which allows expression and/or delivery of said enzymatic molecule within said plant cell.

30. The expression vector of claim 18, wherein 10 said vector comprises:

a) a transcription initiation region;
b) a transcription termination region;
c) an intron;
d) an open reading frame;
15 e) a gene encoding at least one said enzymatic nucleic acid molecule, wherein said gene is operably linked to the 3'-end of said open reading frame; and wherein said gene is operably linked to said initiation region, said intron, said open reading frame 20 and said termination region, in a manner which allows expression and/or delivery of said enzymatic molecule within said plant cell.

31. A transgenic plant comprising nucleic acid 25 molecule encoding for an enzymatic nucleic acid molecule with RNA cleaving activity, wherein said nucleic acid molecule modulates the expression of a gene involved in the biosynthesis of alkaloid in said plant .

30 32. The transgenic plant of Claim 31, wherein said gene is solanidine UDP-glucose glucosyl-transferase.

33. The transgenic plant of Claim 31, wherein the plant is transformed with Agrobacterium, bombarding with

DNA coated microparticles, whiskers, or electro-poration.

34. The transgenic plant of Claim 33, wherein said
5 bombarding with DNA coated microparticles is done with
the gene gun.

35. The transgenic plant of Claim 31, wherein said
plant contains a selectable marker selected from the
10 group consisting of chlorosulfuron, hygromycin, bar gene,
bromoxynil, and kanamycin and the like.

36. The transgenic plant of Claim 31, wherein said
nucleic acid is operably linked to a promoter selected
15 from the group consisting of octopine synthetase, the
nopaline synthase, the manopine synthetase, cauliflower
mosaic virus (35S); ribulose-1, 6-biphosphate (RUBP)
carboxylase small subunit (ssu), the beta-conglycinin,
the phaseolin promoter, napin, gamma zein, globulin, the
20 ADH promoter, heat-shock, actin, and ubiquitin.

37. The transgenic plant of Claim 31, said
enzymatic nucleic acid molecule is in a hammerhead, hair-
pin, hepatitis Δ virus, group I intron, group II intron,
25 VS nucleic acid or RNaseP nucleic acid configuration

38. The transgenic plant of Claim 31, wherein said
enzymatic nucleic acid with RNA cleaving activity encoded
as a monomer.

30

39. The transgenic plant of Claim 31, wherein said
enzymatic nucleic acid with RNA cleaving activity encoded
as a multimer.

40. The transgenic plant of Claim 31, wherein the nucleic acids encoding for said enzymatic nucleic acid molecule with RNA cleaving activity is operably linked to the 3' end of an open reading frame.

5

41. An enzymatic nucleic acid molecule with RNA cleaving activity, wherein said nucleic acid molecule modulates the expression of a plant gene involved in the flower formation.

10

42. The enzymatic nucleic acid molecule of claim 41, wherein said plant is a potato plant.

43. The enzymatic nucleic acid molecule of claim 15 41, wherein said plant is selected from a group consisting of Lettuce, spinach, cabbage, brussel sprouts, arugula, kale, collards, chard, beet, turnip, sweet potato and turfgrass.

20 44. The enzymatic nucleic acid molecule of claim 41, wherein said nucleic acid is in a hammerhead configuration.

25 45. The enzymatic nucleic acid molecule of claim 41, wherein said nucleic acid is in a hairpin configuration.

30 46. The enzymatic nucleic acid molecule of claim 41, wherein said nucleic acid is in a hepatitis δ virus, group I intron, group II intron, VS nucleic acid or RNaseP nucleic acid configuration.

47. The enzymatic nucleic acid of claim 41, wherein said nucleic acid comprises between 12 and 100 bases complementary to RNA of said gene.

5 48. The enzymatic nucleic acid of claim 41, wherein said nucleic acid comprises between 14 and 24 bases complementary to RNA of said gene.

10 49. The enzymatic nucleic acid of claim 44, wherein said hammerhead comprises a stem II region of length greater than or equal to two base-pairs.

15 50. The enzymatic nucleic acid of claim 45, wherein said hairpin comprises a stem II region of length between three and seven base-pairs.

51. The enzymatic nucleic acid of claim 45, wherein said hairpin comprises a stem IV region of length greater than or equal to two base-pairs.

20 52. The enzymatic nucleic acid of claim 41, wherein said gene is citrate synthase.

25 53. The enzymatic nucleic acid molecule of claim 52, wherein said nucleic acid specifically cleaves any of sequences shown in Table V, wherein said nucleic acid is in a hammerhead configuration.

30 54. The enzymatic nucleic acid molecule of claim 52, wherein said nucleic acid specifically cleaves any of sequences shown in Table VI, wherein said nucleic acid is in a hairpin configuration.

55. The enzymatic nucleic acid molecule of any of claims 53 or 54, consisting essentially of one or more sequences selected from the group shown in Tables V and VI.

5

56. A plant cell comprising the enzymatic nucleic acid molecule of claim 41.

57. A transgenic plant and the progeny thereof, 10 comprising the enzymatic nucleic acid molecule of claim 41.

58. An expression vector comprising nucleic acid encoding the enzymatic nucleic acid molecule of claim 41, 15 in a manner which allows expression and/or delivery of that enzymatic nucleic acid molecule within a plant cell.

59. An expression vector comprising nucleic acid encoding a plurality of enzymatic nucleic acid molecules 20 of claim 41, in a manner which allows expression and/or delivery of said enzymatic nucleic acid molecules within a plant cell.

60. A plant cell comprising the expression vector 25 of claim 58.

61. A plant cell comprising the expression vector of claim 59.

30 62. A transgenic plant and the progeny thereof, comprising the expression vector of claim 58.

63. A transgenic plant and the progeny thereof, comprising the expression vector of claim 59.

64. A method for modulating expression of an gene in a plant by administering to said plant the enzymatic nucleic acid molecule of claim 41.

5

65. The method of claim 64, wherein said plant is a potato plant.

66. The method of claim 64, wherein said gene is
10 citrate synthase.

67. The expression vector of claim 58, wherein said vector comprises:

15 a) a transcription initiation region;
b) a transcription termination region;
c) a gene encoding at least one said enzymatic nucleic acid molecule; and

wherein said gene is operably linked to said initiation region and said termination region, in a
20 manner which allows expression and/or delivery of said enzymatic molecule within said plant cell.

68. The expression vector of claim 58, wherein said vector comprises:

25 a) a transcription initiation region;
b) a transcription termination region;
c) an open reading frame;
d) a gene encoding at least one said enzymatic nucleic acid molecule, wherein said gene is operably
30 linked to the 3'-end of said open reading frame; and
wherein said gene is operably linked to said initiation region, said open reading frame and said termination region, in a manner which allows expression

and/or delivery of said enzymatic molecule within said plant cell.

69. The expression vector of claim 58, wherein
5 said vector comprises:

- a) a transcription initiation region;
- b) a transcription termination region;
- c) an intron;
- d) a gene encoding at least one said enzymatic
10 nucleic acid molecule; and

wherein said gene is operably linked to said initiation region, said intron and said termination region, in a manner which allows expression and/or delivery of said enzymatic molecule within said plant
15 cell.

70. The expression vector of claim 58, wherein
said vector comprises:

- a) a transcription initiation region;
- b) a transcription termination region;
- c) an intron;
- d) an open reading frame;
- e) a gene encoding at least one said enzymatic
nucleic acid molecule, wherein said gene is operably
25 linked to the 3'-end of said open reading frame; and

wherein said gene is operably linked to said initiation region, said intron, said open reading frame and said termination region, in a manner which allows expression and/or delivery of said enzymatic molecule
30 within said plant cell.

71. A transgenic plant comprising nucleic acid molecule encoding for an enzymatic nucleic acid molecule with RNA cleaving activity, wherein said nucleic acid

molecule modulates the expression of a gene involved in flower formation in said plant.

72. The transgenic plant of Claim 71, wherein said
5 gene is citrate synthase.

73. The transgenic plant of Claim 71, wherein the
plant is transformed with Agrobacteriurn, bombarding with
DNA coated microprojectiles, whiskers, or electro-
10 poration.

74. The transgenic plant of Claim 73, wherein said
bombarding with DNA coated microprojectiles is done with
the gene gun.

15

75. The transgenic plant of Claim 71, wherein said
plant contains a selectable marker selected from the
group consisting of chlorosulfuron, hygromycin, bar gene,
bromoxynil, and kanamycin and the like.

20

76. The transgenic plant of Claim 71, wherein said
nucleic acid is operably linked to a promoter selected
from the group consisting of octopine synthetase, the
nopaline synthase, the manopine synthetase, cauliflower
25 mosaic virus (35S); ribulose-1, 6-biphosphate (RUBP)
carboxylase small subunit (ssu), the beta-conglycinin,
the phaseolin promoter, napin, gamma zein, globulin, the
ADH promoter, heat-shock, actin, and ubiquitin.

30

77. The transgenic plant of Claim 71, said
enzymatic nucleic acid molecule is in a hammerhead,
hairpin, hepatitis δ virus, group I intron, group II
intron, VS nucleic acid or RNaseP nucleic acid
configuration

78. The transgenic plant of Claim 71, wherein said enzymatic nucleic acid with RNA cleaving activity encoded as a monomer.

5

79. The transgenic plant of Claim 71, wherein said enzymatic nucleic acid with RNA cleaving activity encoded as a multimer.

10 80. The transgenic plant of Claim 71, wherein the nucleic acids encoding for said enzymatic nucleic acid molecule with RNA cleaving activity is operably linked to the 3' end of an open reading frame.
